Situation report period covered: 17 February to 15 March 2024

This report provides an update of the high pathogenicity avian influenza (HPAI) situation, according to the information submitted through the World Animal Health Information System of the World Organisation for Animal Health (WAHIS) between 17 February and 15 March 2024 (4-week period).

Key messages

The period covered by this report is marked by an unprecedented milestone in HPAI evolution, with reports of its first detection on Antarctica’s mainland, in its northern tip. This evolution is of particular concern, as experts fear that the negative impact of HPAI on Antarctic wildlife and biodiversity could be immense. WOAH also continues to pay close attention to the Antarctic region and is calling on the animal health community to monitor the situation.

Also, the current HPAI epidemic season continues with 21 outbreaks being reported in poultry and 62 in non-poultry birds over the 4 weeks covered by the report, in Africa, Americas, Asia and Europe. About 405,000 poultry birds died or were culled worldwide mostly in Europe during the 4 weeks period. Based on the known seasonal pattern of the disease, it is possible that we have just passed the peak of the global epidemic wave in poultry (to be confirmed, depending on how the disease evolves over the coming months). However, the number of outbreaks in poultry is expected to remain relatively high worldwide for several months yet, as there is usually a gradual reduction over the first half of the year. In addition, each region or sub-region may have its own seasonal specificities which differ from the general global trend.

Outbreaks in mammals continued to be reported in Americas and Europe during the 4 weeks covered by the report. WOAH stresses the importance of reporting outbreaks of avian influenza in unusual hosts, as the virus has been increasingly detected in mammals in recent months.

WOAH recommends that countries maintain their surveillance efforts, implement biosecurity and preventive measures at farm level, and continue timely reporting of avian influenza outbreaks in both poultry and non-poultry species.

High quality of information is key to support prevention and rapid response to HPAI.

Situation in the sub-Antarctic and Antarctic regions

The spread of HPAI in the sub-Antarctic and Antarctic regions is of particular concern for wildlife and biodiversity. On 21 December 2023, OFFLU (WOAH/Food and Agriculture Organization (FAO) Network of Expertise on Animal Influenza) published a statement on the continued spread of HPAI H5 in wildlife in South America and its incursion into the sub-Antarctic region. The report summarised the spread and impact of HPAI H5 clade 2.3.4.4b in South America, its incursion into South Georgia and the risk of further spread in the Antarctic region. It pointed out that "the negative impact of HPAI H5 on Antarctic wildlife could be immense".

New cases had continued to be reported in the sub-Antarctic region since October 2023. On 12 March 2024, WOAH received an official report confirming that HPAI reached an unprecedented milestone with the first detection on Antarctica’s mainland, in its northern tip. The discovery came through the identification of the virus in a South Polar skua collected by Argentinian scientists near Argentina’s Antarctic research base in January 2024. Skuas, large seabirds breeding in sub-Antarctic and Antarctic zones, migrate farther north when not breeding, which could spread the disease.

WOAH is closely monitoring the situation in the Antarctic region and is calling on the animal health community to monitor the situation. In September 2023, the WOAH Director General sent a communication to the Delegates of Members in the Americas located in the southern hemisphere to encourage them to report cases of HPAI in Antarctic wildlife and to provide them with notification procedures to share with the competent agents. See WOAH statement for more information. Figure 1 shows the HPAI outbreaks reported in the South of Latin America, Sub-Antarctica, and Antarctic regions since 2022.
Seasonal trend

One of the major changes in the dynamics of HPAI in recent years has been its seasonal nature. Traditionally, the global seasonality of HPAI in poultry was as follows: the spread was lowest in September, began to increase in October and peaked in February\(^1\). This seasonality pattern was mainly influenced by countries in the northern hemisphere. Every year since 2005, the majority of outbreaks have occurred in the northern hemisphere, except, according to WAHIS data, in 2008, 2009 and 2019, the three years in which Indonesia was the country that reported the highest number of poultry outbreaks.

Figure 2 focuses on poultry and shows the seasonality of HPAI separately for the northern and southern hemispheres. For the northern hemisphere (Figure 2a), given that more than 180 outbreaks have been notified each year since 2005, a comparison between the seasonal pattern for 2023 and the seasonal pattern observed between 2005 and 2019 has been provided, based on the number of outbreaks notified to WOAH. To compare seasonality between years, the number of outbreaks was centred and scaled by calendar year. The average was then computed for each month of the period between 2005 and 2019. The figure shows that the peak traditionally observed in February at a global level has shifted to January and that the increase traditionally starting in October has remained in place.

For the southern hemisphere (Figure 2b), as outbreaks have been rarer over time, only the seasonal profile for 2023 is presented, based on the raw number of outbreaks notified to WOAH. In that year, 217 outbreaks were notified by five countries in South America (Argentina, Bolivia, Chile, Ecuador, and Peru) and two countries in eastern and southern Africa (Mozambique and South Africa). The graph shows an initial small peak in February (corresponding to the peak in South America); then the spread began to increase again in July and reached a higher peak in September (corresponding to the peak in South Africa).

The red rectangle indicates where we currently are in the 2024 cycle based on the period covered in “recent updates” below.

---

Figure 2. Number of HPAI outbreaks in poultry reported to WOAH for 2023, by month and by hemisphere. For the northern hemisphere (2a), the 2023 distribution is compared to the distribution for the period between 2005 and 2019. Values were centred and scaled each year, for comparability; the average was then computed for each month of the period between 2005 and 2019. For the southern hemisphere (2b), only the 2023 distribution is presented, based on the raw number of outbreaks. The comparison with 2005–2019 is not shown as outbreaks were rare in the southern hemisphere during this period.

In Europe, an unprecedented number of HPAI virus detections were reported in wild and domestic birds from June to September 2022, according to the European Food Safety Authority (EFSA)\(^2\). European countries/territories reported 118 outbreaks in poultry and 781 outbreaks in wild birds via WAHIS for the summer of 2022. The number of reported outbreaks in wild birds has been particularly high; whereas there were between 0 and 80 outbreaks each summer (June–September) during the period 2017–2021, the number of outbreaks increased to an unprecedented level in 2022. Between June and September 2023, the number of outbreaks in wild birds remained very high, with 648 outbreaks reported. This shows that, since 2022, the virus has persisted in wild birds in Europe during the summer, whereas it was rarely detected in previous summers.

**Recent updates (17/02/2024-15/03/2024)**

To describe the current disease situation of HPAI in poultry and in non-poultry birds, this section covers: (a) a list of new events\(^3\) which started during the 4-week period (reported through immediate notifications); (b) information on events that started before the 4-week period but were still ongoing during that period; (c) the geographic distribution of new outbreaks\(^4\) that started during the 4-week period and d) events which started before the 4-week period but were reported during the 4-week period. The different subtypes of HPAI circulating during the 4-week period are also listed below. This information is based on the immediate notifications and follow-up reports received by WOAH.

---

\(^3\) As defined in Article 1.1.2. of the WOAH Terrestrial Animal Health Code, an “event” means a single outbreak or a group of epidemiologically related outbreaks of a given listed disease or emerging disease that is the subject of a notification. An event is specific to a pathogenic agent and strain, when appropriate, and includes all related outbreaks reported from the time of the initial notification through to the final report. Reports of an event include susceptible species, the number and geographical distribution of affected animals and epidemiological units.

\(^4\) As defined in the glossary of the WOAH Terrestrial Animal Health Code, an “outbreak” means the occurrence of one or more cases in an epidemiological unit.
HPAI in poultry

New events by world region (reported through immediate notifications)

**Africa**
- H5N1
- A recurrence started in Burkina Faso (Centre) on 1 March 2024.

**Europe**
- H5N1
- A recurrence started in Norway (Rogaland) on 17 February 2014
- A recurrence started in Italy (Veneto) on 19 February 2024

**Asia, Americas, and Oceania**
- No new events reported.

On-going events for which there were new reported outbreaks, by world region (reported through follow-up reports):

**Africa**
- H5N1
- Nigeria

**Americas**
- H5N1
- Ecuador, United States of America

**Asia**
- H5N1
- Japan

**Europe**
- H5N1
- Bulgaria, Poland, Romania

**Oceania**
- No new outbreaks reported in the on-going events, or no on-going events.

New outbreaks and associated subtypes

During the period covered by this report, a total of 21 new outbreaks in poultry were notified by 10 countries (Bulgaria, Burkina Faso, Ecuador, Italy, Japan, Nigeria, Norway, Poland, Romania, United States of America). Details are presented in Figures 3 and 4.
High Pathogenicity Avian Influenza (HPAI) – Situation Report

Figure 3. Distribution of HPAI new outbreaks in poultry, and corresponding subtypes

Figure 4. Number of new outbreaks and associated losses by geographical region (losses include animals dead and killed and disposed of within outbreaks – they do not include culling around outbreaks).

Events which started before the 4-week period but were reported during the 4-week period (reported through immediate notifications)

**Americas**
- **H5**
  - A recurrence started in Peru (La Libertad) on 1 February 2024.
- **H7N3**
  - A recurrence started in Mexico (Aguascalientes, Guanajuato, Jalisco, Michoacán, Zacatecas) on 1 February 2024.

**Europe**
- **H5N1**
  - Two recurrences started in Moldova (Clade 2.3.4.4b; Lineage: Fully Eurasian): 
    - One in Orhei on 1 February 2024.
The other one in Cahul on 14 February 2024.

**Africa, Asia, and Oceania**
No events reported.

### HPAI in non-poultry

**New events by world region (reported through immediate notifications)**

- **Africa, Americas, Asia, Europe, and Oceania**
  No new events reported.

**On-going events for which there were new reported outbreaks, by world region (reported through follow-up reports):**

- **Americas**
  - H5N1 in non-poultry birds
  - Brazil, United States of America
  - H5N1 in mammals
  - United States of America (striped skunk, *Mephitis mephitis*)

- **Asia**
  - H5N1 in non-poultry birds
  - Japan

- **Europe**
  - H5 in non-poultry birds
  - Sweden
  - H5N1 in non-poultry birds
  - Austria, Czech Republic (Clade 2.3.4.4b - Lineage: Fully Eurasian), Denmark, Germany, Hungary, Poland, Romania, Slovenia (Clade 2.3.4.4b - Lineage: Fully Eurasian), Ukraine
  - H5N5 in non-poultry birds
  - United Kingdom
  - H5N5 in mammals
  - Norway (red fox, *Vulpes vulpes*)

- **Africa, and Oceania**
  No new outbreaks reported in the on-going events, or no on-going events.

### New outbreaks

During the period covered by this report, a total of 62 outbreaks in non-poultry birds were reported through WAHIS by 15 countries (Austria, Brazil, Czech Republic, Denmark, Germany, Hungary, Japan, Norway, Poland, Romania, Slovenia, Sweden, Ukraine, United Kingdom, United States of America). Details are presented in Figures 5 and 6.
Figure 5. Distribution of HPAI new outbreaks in non-poultry animals reported through WAHIS, and corresponding subtypes.

Figure 6. Number of new outbreaks reported through WAHIS by geographical region

Events which started before the 4-week period but were reported during the 4-week period (reported through immediate notifications or through emails)

**Antarctica**
- H5 in non-poultry birds
  - The first occurrence in the continent started on 21 January 2024.

**Americas**
- H5N1 in non-poultry birds
  - A recurrence started in Canada (Manitoba) on 1 January 2024.

**Asia**
- H5N1 in non-poultry birds
  - A recurrence started in Cyprus (Manitoba) on 2 February 2024.

**Europe**
H5 in non-poultry birds
A recurrence started in Sweden (Partille) on 5 February 2024
H5N5 in non-poultry birds
A recurrence started in Germany (Niedersachsen) on 16 February 2024
H5N5 in mammals
A recurrence started in Norway (Troms Og Finnmark) on 16 February 2024 (red fox, *Vulpes vulpes*)

Africa, and Oceania
No new events reported.

Other cases in mammals by world region (reported through emails)

Africa, Americas, Asia, Europe, and Oceania
No new cases reported.

Self-declarations of freedom submitted during the 4-week period

In accordance with the provisions of the *Terrestrial Animal Health Code*, Members may wish to self-declare the freedom of their country, zone or compartment from HPAI. A Member wishing to publish its self-declaration for disease-freedom, should provide the relevant documented evidence of compliance with the provisions of the Code.

No Member submitted a self-declaration for HPAI during the 4 weeks covered by this report.

Epidemiological background

High pathogenicity avian influenza (HPAI) is caused by influenza A viruses in the family Orthomyxoviridae. Since its identification in China (People’s Rep. of) in 1996, there have been multiple waves of intercontinental transmission of the H5Nx Gs/GD lineage virus. HPAI has led to the death and mass slaughter of over 557 million poultry worldwide between 2005 and 2023, with an unprecedented peak of 141 million in 2022. During this peak in 2022, more than 85 countries and territories in the world were affected with HPAI. In addition, up to now, humans have occasionally been infected with subtypes H5N1 (around 870 cases reported, of which half died), H7N9 (around 1,500 cases reported, of which about 600 died), H5N6 (around 80 cases reported, of which about 30 died), H9N2 (around 80 cases reported, of which 2 died) and sporadic cases have been reported with subtypes H3N8, H7N4, H7N7 and H10N3.
